Pre-Reading: Correction for "PyTorch Linear Regression Training Slope and Bias"

This reading material addresses a factual error in the video "PyTorch Linear Regression Training Slope and Bias." Students should read this correction before watching the video to ensure a clear understanding of the concepts discussed.

Transcript error in third-to-last sentence:

In the video, there is a factual error in the third-to-last sentence where it is stated: "The gradient is parallel to the contour lines and points to the direction of greatest change." This statement is incorrect. The gradient actually points **perpendicular** to the contour lines, not parallel.

Revised explanation:

The gradient of a function represents the direction of the steepest ascent or the direction in which the function increases most rapidly. It is always perpendicular (normal) to the contour lines of the function, which are lines where the function has a constant value. Thus, when performing gradient descent, the algorithm follows the negative gradient direction, which is perpendicular to the contour lines, to find the minimum point on the cost surface.

Understanding that the gradient is perpendicular to contour lines is crucial for correctly applying gradient descent in machine learning models. Please keep this correction in mind while watching the video to avoid any misconceptions.
